(Received 21 October, 2023; Accepted 29 December, 2023)

ABSTRACT

The present study emphasizes on groundwater quality assessment and working out the interrelationship between various physico-chemical parameters and potentially toxic elements in low-hills of Himachal Pradesh. The study was conducted in industrial areas of two districts and a total of 240 groundwater samples were collected during 2020-2022 from borewells and handpumps and analyzed 21 parameters such as temperature, turbidity, TDS, EC, pH, DO, BOD, alkalinity, sulphate, nitrate, sodium, calcium, total hardness, chloride, magnesium, manganese, iron, zinc, copper, chromium, and lead. The study area was divided into five locations in both the districts and samples were taken during pre-monsoon and post-monsoon to check the seasonal variation. The estimated values were then compared with drinking water quality standards prescribed by BIS and location-wise WQI value was calculated. The results showed that in both the districts, the physico-chemical parameters under study were within the permissible limits. The WQI values range from 43.85 to 25.85 in district Sirmaur and 39.18 to 25.60 in district Una. In both the districts, the WQI lies under the good to excellent category and were suitable for human consumption. Location-wise, the highest WQI value was highest around the industries followed by samples within the industry > along the main highway > residential areas, and the lowest value was in the control which was the samples taken from the Department of Irrigation and Public Health supply. Seasonal-wise, the concentration of the physico-chemical parameters as well as the WQI was higher during post-monsoon than pre-monsoon.

Key words: Groundwater quality, WQI, Low-hills

Introduction

Groundwater quality is one of the most important aspects of any water resource study (Ackah *et al.* 2011). The increasing evidence of groundwater contamination in recent years coupled with human health concerns and ecological effects of contaminants such as nitrate, and pesticides have heightened the pressure on public agencies to improve groundwater quality. Utilization of land varies from place to place due to rapid urbanization and indus-

trialization, causing a lot of variation in the quality of the groundwater within a short distance (Rao, 2006). Groundwater quality variation in any area is a function of physicochemical quality parameters which are greatly influenced by the geological formations and anthropogenic activities of the area (Subramni *et al.*, 2005). The water quality index (WQI) is one of the most effective tools to assess the quality of water for concerned citizens and policy makers (Ramakrishnaiah *et al.*, 2008).

Due to rapid industrialization and urbanization

(¹Ph.D. Student, ² Professor)

in districts Sirmaur and Una, it was important to study the impacts on groundwater. According to (Central Groundwater Board, 2013a), the stage of groundwater development in Kala Amb valley was 564.63% as on 2011 and fell under “*Over Exploited category*” and the net groundwater availability for future irrigation purposes was 0.00-hectare metre. Further, in Una district, due to extensive groundwater development for irrigation and the recently set up industrial units, the water levels likely to show a depleting trend. As of March 2011, the stage of groundwater development in the Una valleys of the district was 108% and fell under “*Critical category*” of development (Central Groundwater Board, 2013b). A number of studies have been conducted to assess the quality of groundwater but the effect of industries on groundwater quality in low hills is rare, hence the present study was planned. The industrial area particularly lying in the low hills of district Sirmaur and district Una of Himachal Pradesh has been taken for the present study. The objective of the present study is to assess the various physico-chemical parameters to obtain Water Quality Index and to find out interrelationships between the various parameters.

Materials and Methods

Study Area

The present study is conducted in industrial areas of districts Sirmaur and Una lying in the low hills of Himachal Pradesh, India. Kala-Amb industrial area in Sirmaur district and Mehatpur industrial areas in Una district have been selected for the current study as there has been a significant increase in the number of industries in the area since 1980 when a large number of industries were established. A detailed map of the study area is presented in Figure 1. The Sirmaur district is the southernmost district of Himachal Pradesh having a geographical area of 2825 km² and lies between North latitude of 31°01'00" to 30°22'00" and East longitude of 77°01'00 to 77°50'00". The climate of the Sirmaur district is sub-tropical to temperate depending upon the elevation. The Average annual rainfall in the district is about 1405 mm, out of which 90% occurs during the monsoon season. The mean maximum and minimum temperatures of 30°C and -0°C respectively experienced in the district.

Una district is situated in the southwestern part

of the state of Himachal Pradesh. The district Una has a geographical area of 1540 km² and covers 2.8% area of the total area of the State. It lies between 31°18'00" to 31°55'00" N latitude and 75°55'00" to 76°28'00" E longitude and has elevations ranging from 340m to 1041m above mean sea level. The climate of the Una district is tropical to temperate in nature, as the terrain varies from plains to high hills. Temperature varies from a minimum of 4°C in winter to a maximum of 46°C in summer. The area receives rainfall during the monsoon period, extending from June to September, and also during the non-monsoon period. The annual average rainfall in the area is about 1040 mm, with about 55 average rainy days. The winter season starts in November and continues till the middle of March.

Sampling of groundwater and analysis

The present study was conducted in the Kala-Amb and Mehatpur industrial areas of District Sirmaur and Una respectively during the period 2020-2022. In these districts, five locations were randomly selected and replicated three times each. The groundwater samples were collected in two different seasons (pre-monsoon and post-monsoon) from handpumps and borewells thus making a total of

Groundwater quality parameters in district Sirmaur

Table 1. Water Quality Index range

Water Quality Index Level	Water Quality Status	Water Quality Grading	Possible uses
0-25	Excellent	A	Drinking, irrigation and industrial purpose
26-50	Good	B	Drinking, irrigation and industrial purpose
51-75	Poor	C	Irrigation and industrial purpose
79-100	Very poor	D	For irrigation purpose
>100	Unsuitable for drinking and fish culture	E	Proper treatment required for any kind of usage

240 samples during the whole study period. In District Sirmaur, the depth of handpumps was 50-60 m and borewells were 90-120 m while in District Una, handpumps depth was 10-25 m and depth of borewells was 40-70 m. The collected samples were then analysed for various physico-chemical parameters such as temperature, turbidity, total dissolved

solids, electrical conductivity, pH, dissolved oxygen, biochemical oxygen demand, alkalinity, sulphate, nitrate, sodium, calcium, total hardness, chloride, magnesium, manganese and potentially toxic elements such as iron, zinc, copper, chromium, and lead using standard procedures recommended by (APHA 2012). The WQI was calculated using the

Weighted Arithmetic Water Quality Index Method where each of the parameters was assigned a weight (w_i) according to its relative importance in the overall quality of water for drinking purposes.

Observation

1. The relative weight (W_i) was computed from the equation:

$$W_i = \frac{w_i}{\sum w_i}$$

2. A quality rating scale (q_i) was calculated by

$$q_i = (C_i/S_i) \times 100$$

where, C_i is concentration of each parameter in the water sample

S_i is Indian drinking water standard for each parameter

3. Sub-index is then calculated as

$$SL_i = W_i \times q_i$$

where, SL_i is sub index of i^{th} parameter

WQI is then calculated as

$$WQI = \sum SL_i$$

Results and Discussion

The normal statistics of the groundwater quality parameters in study for districts Sirmaur and Una have been presented in Tables 4 and 5 respectively. All of the physico-chemical parameters in the study

area were within the permissible limits given by BIS (Table 3). This indicated that even though a number of industrial as well as anthropogenic activities have been going on in the area, the level of water contamination was confined to surface or sub-surface level and has not yet penetrated to groundwater.

Physical parameters

The temperature in district Sirmaur ranged from 21.4°C to 19.6°C during pre-monsoon and 21.5°C to 19.7°C during post-monsoon and turbidity was very low with an arithmetic mean of 2.07 NTU and 2.2 NTU during pre-monsoon and post-monsoon respectively indicating that the groundwater was quite clear and there was the less suspended matter (Table 4). The TDS ranged from 589 to 140 mg l⁻¹ during pre-monsoon and 506 to 139 mg l⁻¹ during post-monsoon. The degree of groundwater quality can be classified as fresh if the TDS value is less than 1,000 mg l⁻¹ brackish if TDS value lies between 1,000 mg l⁻¹ and 10,000 mg l⁻¹; saline if TDS value varied from 10,000 mg l⁻¹ to 1,000,000 mg l⁻¹ and brine if TDS is more than 1,000,000 mg l⁻¹ (Todd 1980). Thus, the groundwater samples from the current study fall under the fresh category as all the TDS values are under 1,000 mg l⁻¹. The standard deviation of TDS was found to be 88.671 during pre-monsoon and

76.861 during the post-monsoon season which was higher than the other parameters. This indicates that the values of the samples differ widely from the mean.

Chemical parameters

The pH ranged from 8.8 to 7.1 during pre-monsoon and 8.9 to 7.2 during post-monsoon showing a slightly alkaline range of pH in district Sirmaur. In district Sirmaur, the mean concentration of EC was 0.522 dS m⁻¹ during pre-monsoon and 0.463 dS m⁻¹ during post-monsoon. Alkalinity was found in the range of 116 to 82 mg l⁻¹ during pre-monsoon and 146 mg l⁻¹ to 80 mg l⁻¹ during post-monsoon. Alkaline water may decrease the solubility of metals and varies in accordance with fluctuations in the pollution load (Parashar *et al.*, 2006). Sulphate concentration on average was 54.531 mg l⁻¹ during pre-monsoon and 51 mg l⁻¹ during post-monsoon showing a very less seasonal variation. The mean value of nitrate in the groundwater was observed between 5.8 mg l⁻¹ during pre-monsoon and 5.1 mg l⁻¹ during post-monsoon. Epidemiological evidence suggests that nitrate-nitrogen exposure in water is strongly associated with diseases like methemoglobinemia, gastric cancer, thyroid diseases, and diabetes (Krishna *et al.*, 2011). It was an indication of good water quality as

all the samples collected were within the desirable limit of 45 mg l⁻¹ as given by BIS. Calcium and magnesium are directly related to the hardness of water and these ions may exist mainly as bicarbonates or in the form of sulphate and chloride to a lesser degree (Kumar *et al.*, 2014). The concentration of calcium ranged between 74 mg l⁻¹ to 15 mg l⁻¹ during pre-monsoon and 59 mg l⁻¹ to 31 mg l⁻¹ during post-monsoon while magnesium concentration ranged from 35.6 mg l⁻¹ to 9.5 mg l⁻¹ during pre-monsoon and 22.8 mg l⁻¹ to 6.1 mg l⁻¹ during post-monsoon. Chloride in groundwater may come from diverse sources such as weathering, leaching of sedimentary rocks and soil as well as domestic and municipal effluents (Prasant *et al.*, 2012). The mean concentration of chloride was 52 mg l⁻¹ during pre-monsoon and 48 mg l⁻¹ during post-monsoon. Seasonal variations showed that the concentrations of all the physico-chemical parameters in the study area were lower in the post-monsoon season than the pre-monsoon season. Yashoda *et al.* (2014) also found similar seasonal variations in physico-chemical characteristics of groundwater in industrial areas in Vishakhapatnam.

Heavy metals

The mean concentration of iron was 0.16 mg l⁻¹ dur-

ing pre-monsoon and 0.12 mg l⁻¹ during post-monsoon while that of zinc was 0.078 mg l⁻¹ during pre-monsoon and 0.064 mg l⁻¹ during post-monsoon. The concentration of copper was in the range of 0.045 mg l⁻¹ to 0.011 mg l⁻¹ during pre-monsoon and 0.039 mg l⁻¹ to 0.013 mg l⁻¹ during post-monsoon. Chromium showed a mean concentration of 0.24 mg l⁻¹ and 0.23 mg l⁻¹ during pre-monsoon and post-monsoon respectively. Lead concentration was in the range of 0.015 mg l⁻¹ to 0.001 mg l⁻¹ during pre-monsoon and 0.014 mg l⁻¹ to 0.005 mg l⁻¹ during post-monsoon. The concentration of heavy metals in the groundwater was within the permissible limits given by BIS.

Groundwater quality parameters in district Una

Physical parameters

The temperature of the groundwater samples in district Una ranged from 21.3 °C to 19.6 °C during pre-monsoon and 21.7 °C to 19.4 °C during post-monsoon. Turbidity ranged from 2.98 to 1.04 NTU during pre-monsoon and 2.7 to 1.4 NTU during post-monsoon which also indicates a very less presence of suspended matter. TDS showed a wide range with a standard deviation of 72.318 during pre-monsoon and 62.114 during post-monsoon. The TDS values were also under 1,000mg l⁻¹ in district Una thus, the samples can be classified as fresh according to Todd, (1980).

Chemical parameters

Similarly, the pH in district Una was slightly alkaline and its value ranged from 8.8 to 7.2 during pre-monsoon and 8 to 7.1 during post-monsoon (Table 5). EC ranged from 0.722 dS m⁻¹ to 0.345 dS m⁻¹ during pre-monsoon and 0.714 dS m⁻¹ to 0.339 dS m⁻¹

during post-monsoon. Alkalinity ranged from 111 mg l⁻¹ to 81 mg l⁻¹ during pre-monsoon and 103 mg l⁻¹ to 82 mg l⁻¹ during post-monsoon which indicated that the concentrations were below the desirable limit prescribed by BIS. Sulphate showed a wide seasonal variation with an arithmetic mean of 55 mg l⁻¹ during pre-monsoon and 36 mg l⁻¹ during post-monsoon. Nitrate concentration ranged from 7.4 to 4.3 mg l⁻¹ during pre-monsoon to 2.8 to 1.1 mg l⁻¹ during post-monsoon. Calcium concentration ranged between 68 mg l⁻¹ to 33 mg l⁻¹ during pre-monsoon and 47 mg l⁻¹ to 22 mg l⁻¹ during post-monsoon and magnesium concentration was between 32.8 to 17.2 during pre-monsoon and 34.6 mg l⁻¹ to 8.5 mg l⁻¹ during post-monsoon. The concentration of total hardness lies between 161 mg l⁻¹ to 42 mg l⁻¹ during pre-monsoon and 94 mg l⁻¹ to 39 mg l⁻¹ during post-monsoon. The mean chloride concentration was 41 mg l⁻¹ for pre-monsoon and 39 mg l⁻¹ for the post-monsoon season.

Heavy metals

The concentration of iron varied from 0.31 mg l⁻¹ to 0.09 mg l⁻¹ during pre-monsoon and 0.29 mg l⁻¹ to 0.08 mg l⁻¹ during post-monsoon. The mean value of zinc was 0.070 mg l⁻¹ during pre and 0.055 mg l⁻¹ during post-monsoon while copper showed a mean value of 0.027 mg l⁻¹ during pre-monsoon and 0.022 mg l⁻¹ during post-monsoon. Chromium and lead also exhibited a concentration lower than the permissible limit prescribed by BIS.

Water Quality Index (WQI) of groundwater

In district Sirmaur, the WQI ranged from 43.85 to 25.85 and comes under good and excellent category.

Table 6. Seasonal variation in WQI of groundwater in low hills of Himachal Pradesh

Seasons Locations	Pre-monsoon	Post-monsoon	Category	Suitability for drinking
District Sirmaur				
S1	43.85	40.76	Good	Suitable
S2	42.18	40.78	Good	Suitable
S3	39.02	38.27	Good	Suitable
S4	38.14	37.02	Good	Suitable
S5	26.91	25.85	Excellent	Suitable
District Una				
U1	39.18	38.47	Good	Suitable
U2	38.40	38.08	Good	Suitable
U3	37.97	37.75	Good	Suitable
U4	37.58	37.55	Good	Suitable
U5	26.89	25.60	Excellent	Suitable

ries. Similarly, in district Una, the groundwater WQI comes under good and excellent categories with values ranging from 39.18 to 25.60 (Table 6). Seasonal variations in both the districts showed that the WQI was higher during the pre-monsoon season than the post-monsoon season. All the groundwater samples taken from different locations were suitable for drinking purposes. Location-wise, the highest WQI in both the districts was found in S1 (around the industries) followed by S2 (within the industries), S3 (along the main highway), S4 (residential areas) and the lowest value was found in the control which was the IPH (Irrigation and Public Health) supply. However, during the post-monsoon season in district Sirmaur, the highest WQI value was found in S2 which was within the industries followed by S1 which was around the industries.

Conclusion

The present study provides insights into the groundwater quality status around the industrial area in the low hills of Himachal Pradesh. The groundwater quality of these areas was assessed by considering important physico-chemical parameters. The concentrations of these parameters in comparison with the standard values of BIS are well within the permissible limits. This indicated that pollution occurring from industrial activities as well as anthropogenic sources have not yet entered into great depths as the groundwater samples were collected from handpumps and borewells of more than 10 m in depth. WQI was computed using these parameters and it has been found that the WQI in both the districts comes under the good to excellent category in both districts Sirmaur and Una. Seasonal variation indicated that the concentration of the parameters as well as WQI was higher during pre-monsoon as compared to post-monsoon. This may be attributed to the inflow of freshwater of good quality during the monsoon season. This study demonstrated that the groundwater quality in the study area in general was good and fit for human consumption. All the parameters were within permissible limits by BIS. However, with increasing industrial and human activities, continuous monitoring of groundwater is required to check any possible contamination and to know the quality status. It is recommended that safe disposal of waste should be practiced in order to prevent groundwater contamination in these areas.
